

Facilitating cross-border collaboration

All-Island Research Observatory

The Challenge

- Collate, analyse and interpret data from north and south of the Irish border
- Make this analysis accessible via the Internet in an easy-to-use format

The Benefits

- Closer collaboration on cross-border projects
- Better informed decision making

The Customer

The All-Island Research Observatory (AIRO) is based at the National University of Ireland Maynooth (NUIM). It was set up under the guidance of the National Institute for Regional and Spatial Analysis (NIRSA) and the National Centre for Geo-Computation (NCG).

The Challenge

Historically, there has been very little collaboration between planning departments in the Republic of Ireland and Northern Ireland. Plans are still generally made for the development of schools, hospitals, utilities and transportation infrastructure – without any consideration of community needs and other development initiatives just a few miles away over the border.

All this is beginning to change.

Now, there is growing appreciation – both north and south of the Irish border – of the importance of sharing information and taking into account the needs of the entire Irish population. *“Roads and services don’t just stop at the border,”* says Justin Gleeson, data and technical manager, AIRO project. *“It makes sense to make decisions for the benefit of the whole island.”*

Obviously there are political reasons why plans were not developed collaboratively in the past. Today, however, cross-border planning is hampered not by politics, but by the absence of data. Gleeson says: *“The lack of comparable, cross-border data seems surprising in today’s modern world and yet, it is extremely difficult to create the all-island datasets required for evidence-informed, cross-border planning.”*

The All-Ireland Research Observatory (AIRO) project was set up in 2008 to address this challenge and make comparable, cross-border data more readily available. The project aimed to: collate and process data from both sides of the border; analyse and interpret it; and then make it accessible via the Internet.

The Solution

From the outset, the AIRO team knew that geographic information system (GIS) technology would play an essential role in the project. *“The whole initiative centres on regional, spatial data analysis, so GIS was key,”* Gleeson says. NUIM uses a wide range of different GIS products from different vendors in its research and education programmes. However, for the AIRO project it elected to use a number of solutions supplied and supported by Esri Ireland.

“ GIS plays a vital role in providing the hard evidence to inform cross-border plans. ”

Justin Gleeson, Data and Technical Manager, AIRO Project

Developing measures of access to services across the island of Ireland

The AIRO project team uses ArcGIS Server to collate, process, analyse and interpret relevant data from Northern Ireland and the Republic of Ireland. It performs demographic analysis and uses tools such as Esri's NetworkAnalyst to examine the accessibility of public services. For example, the project team has mapped the distribution of public facility data right across the island and calculated the average drive time from every residential address point to such services. The team also uses ArcGIS to map the distribution of comparable census information and deprivation indices for the whole of the island.

All of this data analysis is then made accessible on the Internet, via a series of interactive maps of the whole island. This online GIS capability was developed by the AIRO project team and Esri Ireland using Esri's ArcGIS Viewer for Flex, a ready-to-use application that makes it easy for organisations to create customised online mapping applications without the need for programming skills. Planners working anywhere in Ireland can access the AIRO web site, view maps of their own areas of interest and access a wealth of statistical information to support their planning.

Benefits

Without a doubt, the AIRO project has helped to facilitate a new era of cross-border cooperation. Although it is still early days, planners north and south of the border now have greater insight into the needs of all communities across the whole of Ireland. Consequently, they are moving towards a more collaborative approach when planning new services and facilities. *“Things are going in the right direction,”* believes Gleeson. *“There is a lot of cross-border planning going on at the moment and new joint projects are starting up all the time.”*

With the development of its GIS-enabled web site, the AIRO project team has created an invaluable new decision-making tool. Public sector planners can use it to make better planning decisions, which are backed up by accurate, statistical evidence. With more supporting data at their fingertips, planners can locate new services and facilities in the best positions where they will benefit the most people. Gleeson says: *“GIS plays a vital role in providing the hard evidence to inform cross-border plans.”*

The AIRO web site is already widely used and has subscribers from every government department and all local authorities across the country – north and south. On average, around 200 users access the online data every day. However, it is not only the public sector that benefits from the AIRO project. Academics and developers in the private sector can also access the online data to inform their research and development plans.

The AIRO project team has been delighted with the performance and flexibility of the GIS solutions provided by Esri Ireland. *“We can set up new maps in just a couple of hours and don't need heavy programming skills,”* says Gleeson. *“It has become so easy to deliver web mapping, that we are now making much more information accessible online than we originally anticipated. Esri GIS is in many ways shaping the way that the AIRO project is going.”*
